Topic 5

Exam 1

5.1 Exam 1 Review Sheet

- 3/4: Important heterocycles and their key properties.
 - Pyridine.
 - \blacksquare π -deficient ring: δ^+ on α and γ carbons, δ^- at β -carbon.
 - Reactivity.
 - \triangleright EAS: Bad, except as N-oxide.
 - $ightharpoonup S_NAr$: Good, especially at the α -carbons. Electrophile coordination can induce a 10 order of magnitude rate increase (see Figure 2.4), and can even drive dearomatization (as in NAD⁺/NADH).
 - Acidity: $\gamma > \beta > \alpha$ (δ^+ without α -effect, no α -effect, α -effect).
 - Basicity: $pK_a \approx 5.5$ (modulated by substituents).
 - Nucleophilicity: Modulated by substituents (e.g., pyridine vs. DMAP).
 - Pyridine-containing drug: Nicotine.
 - Pyridone.
 - Quinoline.
 - Quinoline-containing drug: Quinine.
 - Isoquinoline.
 - Reactivity.
 - \succ More reactive on non-heterocyclic portion.
 - \succ EAS at 5- and 8-positions.
 - ightharpoonup S_NAr always at 1-position.
 - Quinolone.
 - Quinolone-containing drug: Ciprofloxacin.
 - Pyridazine.
 - Reactivity: Easier to protonate because of unfavorable α -effect (in neutral form).
 - Pyrimidine.
 - Reactivity.
 - \succ Relative to pyridine: Better at S_NAr, worse at EAS.
 - \triangleright More reacrtive at 4- than 2-position (double α -effect is bad).
 - Pyrimidine-containing drug: Anti-asthma agents.
 - Pyrrole.

- Protonation at α -carbons (pK_a = -3.8).
- π -excessive ring: Slightly more reactive toward EAS at α than β -carbons, though can vary depending on the type of carbocation formed??
- Pyrrole-containing drug: Lipitor.
- Imidazole.
 - Hydrogen-bonds well.
 - Undergoes tautomerization.
 - \blacksquare pK_{a 1} = 14.5, pK_{a 2} = 7.1.
 - ightharpoonup Oxazole's pK_a = 0.8, thiazole's pK_a = 2.5 (no equal-energy resonance form).
 - Reactivity: Good at EAS (but not as good as pyrrole).
 - Imidazole-containing natural product: Histidine.
- Pyrazole.
 - Dimeric in solution (due to hydrogen bonding).
 - Tautmerization: Hydrogen prefers to be farther away from bulky substituents.
 - Reactivity.
 - ➤ EAS at 4-position (halogenation, formylation, etc.)
 - Pyrazole-containing drug: DGAT-2 inhibitors.
- Indole.
 - Reactivity.
 - > 5-membered ring is most reactive.
 - ➤ EAS at 3-position.
 - ➤ Basic conditions can make N more nucleophilic than C3 (e.g., for acylation).
 - ightharpoonup Alkylation: C3, C3 ightharpoonup C2, C3 ightharpoonup deprotonation, N.
 - ➤ Deprotonation at C2 (esp. with Boc DMG).
 - $pK_a = 16.2$ for the nitrogen proton.
 - Indole-containing natural product: Strychnine, tryptophan.
- Indazole.
 - Indazole-containing drug: EGFR inhibitor.
- Thiophene.
 - Thiophene-containing natural product: Echinothiophene.
- Furan.
 - Acidity: $pK_a \approx 35.6$ (α -carbons).
 - Furan-containing drug: Zantac.
- Pyridine reactivity.
 - Directed metallation.
 - Lithiation is reversible, hence why it is observed as occurring thermodynamically at the γ -position over kinetically at the α -position.
 - DMGs: All the usual suspects (3° amides, methoxy, carbamates, etc.).
 - DMGs (for π -deficient heterocycles): Halogens and pseudo-halogens (F, Cl, CF₃, CO₂⁻).
 - > Br sometimes included, but may prefer to do lithium/halogen exchange.
 - ➤ MeO is stronger than Cl as a DMG.
 - \blacksquare β -DMGs direct γ (almost all) or α (-OEt).
 - \blacksquare γ -DMGs direct β .
 - \blacksquare α -DMGs direct β .

■ Remember to do these reactions cold, in ethereal solvent (Et₂O or THF), and maybe with an additive (e.g., TMEDA).

- Lithium/halogen exchange.
- Lateral deprotonation.
 - \blacksquare pK_a's:

> γ: 26.

 $\sim \alpha$: 29.5.

 $> \beta$: 33.5.

- Thermodynamic conditions: $\gamma > \alpha > \beta$ -positions.
- Kinetic conditions (e.g., with ⁿBuLi): $\alpha > \gamma > \beta$ -positions.
- Connection to decarboxylation at lateral positions.
- S_NAr is more probable than ketone addition.
 - For example, aqueous ammonia will do S_NAr on pyridine before it adds to a bonded ketone.
- Hydrogenolysis of aryl chlorides.

$$\begin{array}{c|c} Cl & & \\ \hline & H_2 & \\ \hline & Pd/C & \\ N & & \end{array}$$

- Aryl chloride to methyl group.

$$\begin{array}{c|c} & 1. \text{ CH}_2(\text{CO}_2\text{Me})_2, \text{ base} \\ \hline 2. \text{ HO}^-, \Delta & \\ & N & \text{Me} \end{array}$$

- See Figure 1.5.
- Chichibabin (reaction).

$$\begin{array}{c|c}
 & \text{NaNH}_2 \\
\hline
 & 160 \,^{\circ}\text{C, Tol}
\end{array}$$
NH₂

- 2-addition.

$$\overbrace{ \begin{bmatrix} 1. & R'COCl \\ 2. & RMgX \\ 3. & [O] \end{bmatrix}}^{1. & R'COCl}$$

- The Grignard must be aryl, vinyl, or alkynyl.
- It's not clear what the final step oxidant would be, but perhaps DDQ??
- N-oxide formation and removal.

- Oxidants include mCPBA and H_2O_2 .
- N-oxide nitration.

$$\begin{array}{c|c} & & & & NO_2 \\ & & & & \\ & &$$

- N-oxide bromination.

- N-oxide chlorination.

- **Zincke** (reaction).

$$\begin{array}{c|c} Cl & NO_2 & \\ & NO_2 & \\$$

Zincke's salt

- **Zincke** (aldehyde formation).

$$\begin{array}{c|c}
Cl & NO_2 \\
\hline
NO_2 & NHRR' \\
NO_2 & NHRR' \\
NO_2 & NO_2
\end{array}$$

$$\begin{array}{c|c}
NH_2 \\
NO_2 \\
NO_2
\end{array}$$

- Milder, Zincke-inspired meta-halogenation.

$$\begin{array}{c|c} & 1. & Tf_2O, \, HNBn_2 \\ & 2. & NBS \\ & \hline & 3. & NH_4OAc \\ & & N \end{array} \quad \text{Br}$$

- Also works with NIS.
- \blacksquare Works with substituted pyridines, too.
- meta-halogenation via dearomatization.

$$\begin{array}{c|c}
\hline
1. & MeO_2C & \longrightarrow & CO_2Me, & & CI \\
\hline
2. & NCS & & & & \\
3. & HCI & & & & \\
\end{array}$$

- Pyridine synthesis.
 - Industrial pyridine synthesis.

- 1,5-dicarbonyl pyridine synthesis.

$$\begin{array}{c|c} O & O \\ \hline \\ R \end{array} \begin{array}{c} 1. \ \text{NH}_2\text{OH} \\ \hline \\ 2. \ \text{HNO}_3 \end{array} \begin{array}{c} R \\ \hline \\ R \end{array}$$

- **Hantzsch** (pyridine synthesis).

- Mechanism is classic condensation reactions.
- Asymmetric variant: Condense aldehyde and 1,3-dicarbonyl first, then condense with a **vinyligous urethane**. No last-step oxidation needed.
- Kröhnke (pyridine synthesis).

- If R is enolizable (and not methyl), you will get regioisomers.
- Can also start directly with an α -bromocarbonyl compound.
- -[2+2+2] pyridine syntheses: Cool, but limited synthetic utility.
- Some more important pK_a's.
 - ⁿBuLi: 50.
 - LDA: 36.
 - LiNE t_2 : 31.7.
- Pyridone.
 - Chlorination (see Figure 1.4).

$$\begin{array}{c|c} & & & \\ \hline N & & \\ N & & \\ \end{array} \begin{array}{c} &$$

- Cross-coupling.
 - Know generic mechanism.
 - Transmetallation typically occurs through σ -bond metathesis.
 - Kumada (coupling).

$$ArX + RMgX \xrightarrow{L_nPd^0} Ar - R$$

- **Negishi** (coupling).

$$ArX + RZnX \xrightarrow{L_nPd^0} Ar - R$$

- Common solvent: THF.
- Ideal for coupling something to the pyridine α -position; 2-pyridylzincs are great.
- Stille (coupling).

$$ArX + RSnBu_3 \xrightarrow{L_nPd^0} Ar - R$$

Suzuki-Miyaura (coupling).

$$ArX + RB(OH)_2 \xrightarrow{L_nPd^0} Ar - R$$

- Common base: K_2CO_3 .
- Common ligands.
 - ➤ SPhos (see Figure 5.1b).
 - ightharpoonup dppf (sp^3 -hybridized boronates).
 - ➤ Heteroaryl couplings: PCy₃ or MIDA boronates.
- \blacksquare Common solvent: ACN/H₂O.
- Sonogashira (coupling).

$$ArX + R = \frac{L_n Pd^0, CuX}{Et_3N} Ar = R$$

- **Hiyama** (coupling).

$$ArX + RSiMe_3 \xrightarrow{L_nPd^0} Ar - R$$

- Carbonyl enolate (coupling).

$$ArX + \bigvee_{Y} \xrightarrow{L_n Pd^0} Ar \bigvee_{Y}$$

- **Heck** (coupling).

$$ArX + R = \frac{L_n Pd^0}{Et_3 N} Ar = -R$$

- Buchwald-Hartwig (amination).

$$ArX + NHRR' \xrightarrow{L_nPd^0} Ar - NRR'$$

- Carbonylation.

$$ArX + CO + ROH \xrightarrow{L_n Pd^0} ArCOOR \qquad ArX + CO + NHRR' \xrightarrow{L_n Pd^0} ArCONRR'$$

- Via an acyl palladide (ArCOPd) intermediate.
- Ullmann (coupling).

$$ArX + NHRR' \xrightarrow{LCuX} Ar - NRR'$$

- Goldberg (coupling).

$$ArX + RCONH_2 \xrightarrow{LCuX} Ar-NHCOR$$

- **Miyaura** (borylation).

$$ArX + B_2pin_2 \xrightarrow{L_nPd^0} Ar - Bpin$$

- Cyanation.

$$ArX + CN^{-} \xrightarrow{L_n Pd^0} ArCN$$

- **C**-**O** (coupling).

$$\mathrm{ArX} + \mathrm{ROH} \xrightarrow[\mathrm{base}]{\mathrm{L}_n \mathrm{Pd}^0} \mathrm{ArOR}$$

- R can be alkyl or aryl.
- Ligands.

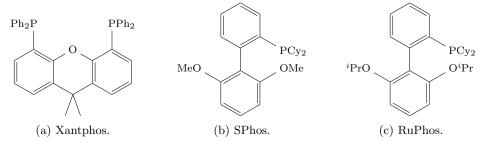

Figure 5.1: Dialkylbiaryl phosphine ligands.

- PPh₃.
- Xantphos (Buchwald-Hartwig amination).
- SPhos (Miyaura borylation and Suzuki-Miyaura borylation).
- RuPhos (Negishi coupling).
- Direct cross-coupling of two (possibly hetero)aryl halides.

$$\begin{array}{c} \text{ArBr} + \text{ArOTf} & \stackrel{\text{*}\text{Bu}}{\overbrace{\hspace{1cm}}^{\text{Ni}}} \\ & \stackrel{\text{Ni}}{\overbrace{\hspace{1cm}}^{\text{Ni}}} \\ & \stackrel{\text{Ph}_2 P}{\overbrace{\hspace{1cm}}^{\text{PPh}_2}} \end{array}$$

- Quinoline reactivity.
 - meta-bromination.

- Proceeds through alternate mechanism.
- 2-addition.

- Hydrogenations.

Figure 5.2: Quinoline hydrogenations.

- *cis*-decalin mostly formed in complete hydrogenation; some *trans*-though.
- Quinoline synthesis.
 - Meth-Cohn (quinoline synthesis): 3-substituted and 2-substitutable quinolines.

- The starting material could come from the (possibly substituted) aniline and acid chloride (plus NEt₃).
- Mechanism: Amide \rightarrow chloroimine \rightarrow enamine \rightarrow attack on a Vilsmeier reagent \rightarrow Friedel-Crafts.
- Skraup (quinoline synthesis): No substitution, mix of (di-)2- and 4-substitution.

$$R^1$$
 R^4 R^4

(b) No pyridine ring substitutions.

Figure 5.3: Skraup quinoline synthesis.

- Figure 5.3a.
 - ightharpoonup If at least one of R^2 , $R^3 = H$, then acid = H_2SO_4 and the system is oxidized to a quinoline.

- ightharpoonup If both $R^2, R^3 \neq H$, then acid = pTsOH and the system is not oxidized.
- Figure 5.3b.
 - ➤ Acrolein generated in situ from glycerol.
- Mechanism: Michael addition, Friedel-Crafts, dehydration, oxidation.
- Friedlander (quinoline synthesis): 2-, 3-, and 4-substitution (or mix and match).

Me

- Mechanism: Imine condensation, followed by enamine attack on the aldehyde/ketone.
- Regioisomer problems: Just reject the unwanted side product.
- Quinolone synthesis.
 - Conrad-Limpach-Knorr (quinolone synthesis).

Figure 5.4: Conrad-Limpach-Knorr quinolone synthesis.

- Presumably also works with substituted variants.
- Acid protonates the more electron-rich ester; heat provides energy for attack at the more electrophilic ketone.
- Isoquinoline reactivity.
 - 5-bromination.

$$\begin{array}{c|c} & \operatorname{Br} \\ & & \\ & \operatorname{AlCl_3} \end{array}$$

- 5- and 8-nitration.

- Chichibabin reaction.

- 1-addition.

$$\begin{array}{c} 1. \text{ RLi} \\ 2. \text{ H}_2\text{O} \\ \hline 3. \text{ [O]} \\ \end{array}$$

- 1-selective S_NAr.

$$\begin{array}{c|c} & & & & & & & \\ & & & & & & & \\ \hline & N & & & & & \\ \hline & N & & & & & \\ \hline & N & & & & & \\ \hline & N & & & & & \\ \hline & N & & & & & \\ \hline & N & & & & & \\ \hline & N & \\ \hline & N & & \\ \hline & N &$$

- Isoquinoline synthesis.
 - Pomeranz-Fritsch (isoquinoline synthesis): Anything can be substituted.

- Can use methyl or ethyl acetal.
- Bischler-Napieralski (isoquinoline synthesis): Enables formation of same derivatives.
- Pictet-Gams (isoquinoline synthesis): Enables formation of same derivatives.
- Pictet-Spengler (reaction): A β -arylethylamine undergoes condensation with an aldehyde or ketone followed by ring closure.

- Mechanism can be Friedel-Crafts or involve shifts (depending on the most nucleophilic position).
- Pyrimidine synthesis.
 - **Grimmaux** (pyrimidine synthesis): 3 carbonyls.

■ Can also use NaOR/ROH and di-R malonate esters.

- **Ziegenbein-Franke** (pyrimidine synthesis): 5- and 6-substituted pyrimidines.

$$\begin{array}{c|c} R^2 & & R^2 \\ \hline & 1. \ DMF \cdot POCl_3 \\ \hline & 2. \ CHONH_2, \ NH_4HCO_2, \ \Delta \end{array} \begin{array}{c} R^2 \\ \hline & N \\ \hline \end{array}$$

- Will have regioselectivity issues if $R^1 \neq R^2$.
- -[3+3] (pyrimidine syntheses).
 - Bis-nucleophile: Pinner product, or other group in the middle besides alkyl.
 - Bis-electrophile.
 - > 4(5)6-substitution: β -diketone.
 - \succ (5)6-substitution, 4-one: β -ketoester.
 - \geq 4(5)-substitution: α, β -unsaturated ketone with β -leaving group.
 - ➤ 6-substitution, 4-one: Propynyl ester.
 - ➤ (5)-substitution: Vinamidium salt.
 - \succ (5)6-substitution, 4-amine: β -ketonitrile.
- Pinner (reaction).

$$R - C \equiv N \xrightarrow{R'OH} R \xrightarrow{C_1^{\ominus} NH_2} H_2O \xrightarrow{R} OH$$

$$OR' NH_3 C_1^{\ominus} NH_2$$

$$Pinner salt R \longrightarrow R$$

$$NH_2$$

$$NH_3$$

$$R \longrightarrow NH_2$$

- Forms **Pinner salts**, which are readily derivatized.
- **Turbogrignard**: The compound ⁱPrMgCl, which is useful for converting R-X to Grignards.
- \bullet KOH + ${
 m H_2O/THF}$ can sometimes be used to convert chloro-heterocycles to carbonyl groups.
- Boc protection/deprotection.

$$R_2NH \xrightarrow{Boc_2O} R_2N - Boc \xrightarrow{TFA} R_2NH$$

- Pyrrole reactivity.
 - 2- (and partial 3-) nitration.

- $AcONO_2$ is a source of NO_2^+ ; made from $HNO_3 + Ac_2O$.
- Perbromination.
